According to Knuth [Knu73, p. 507], this is one of two papers that first discuss the birthday paradox: "if 23 or more people are present in the same room, chances are good that two of them will have the same month and day of birth! In other words, if we select a random function which maps 23 keys into a table of size

365, the probability that no two keys map into the same location is only 0.4927 (less than one-half)." The discovery is credited to unpublished work of H. Davenport (1927). See also [vM39].

This is the author's Ph.D. dissertation. "Secret-key block ciphers are the subject of this work. The design and security of block ciphers, together with their application in hashing techniques, are considered. In particular, iterated block ciphers that are based on iterating a weak round function several times are considered. Four basic constructions for the round function of an iterated cipher are studied.".
